Grant Number: N000140210103

LONG-TERM GOALS

Our long-term goal is to make routine full-depth hydrographic surveys of the ocean orders of magnitude less expensive than they now are so that mesoscale, seasonal, and interannual evolution of ocean structure can be described much more completely than is presently affordable. Higher space-time resolution description of oceanic processes will lead directly to their fuller understanding and prediction.

OBJECTIVES

The objective of this project is to design, construct, and test a long range autonomous underwater glider capable of operating at depths as deep as 6000m while retaining the characteristics of the Seaglider.

APPROACH

The approach is to mimic the successful Seaglider design, but incorporate a hull and buoyancy engine that is capable of operating at full ocean depth. Seaglider (Eriksen et al, 2001) is small and light enough to be launched by hand while having several thousand kilometer range and multi-month mission duration. The vehicle developed in this project, dubbed Deepglider, is expected to have similar characteristics.

WORK COMPLETED

Deepglider development is in the design phase, having started in April, 2002. Design is being carried out by T. J. Osse, the designer of Seaglider. Three hull materials are under consideration: ceramic (alumina), structural amorphous ('liquid') metal, and composite. None of these materials is widely used for pressure hulls, but each shares the characteristic that hulls fabricated from them can be made buoyant, in contrast to using conventional metals (e.g. aluminum, steel, titanium). Vendors for hulls in these materials are comparatively few. Performance, price, and availability considerations will guide the choice among these options. It appears that among the components of Seaglider, the only one that needs substantial change besides the hull is the high pressure valve. We have located a vendor for a suitably small, light, low power use unit.

RESULTS

This project is not sufficiently complete to have results.

IMPACT/APPLICATIONS

Ships have been used for over a century to make deep hydrographic measurements, but at considerable monetary cost. The development of Deepglider will make possible fully autonomous open ocean hydrographic surveys of basic oceanographic fields (temperature, salinity, dissolved oxygen, current) at a small fraction of the cost of using ships. Deepglider is expected to operate for a year for roughly the cost equivalent of one day of oceanographic research vessel time.
